ABSTRACT

The recovery of copper, zinc and rhenium from copper melting dust was investigated using the two-step leaching method. The effects of leaching parameters such as leaching time, liquid/solid ratio, leaching temperature and hydrogen peroxide concentration were studied. Experiments were performed in two stages (1) recovery of copper and zinc, and (2) recovery of rhenium. The optimum leaching conditions for copper and zinc were found as follows: leaching time is 60 min; H₂SO₄ concentration 80 g/L; liquid/solid ratio is 3.0; leaching temperature is 80 °C. Under these conditions, copper and zinc recovering yields were obtained at 90.5% and 92.5%, respectively. Optimum leaching conditions for rhenium were also achieved as follows: leaching time is 90 min; liquid/solid ratio is 3.0 mL/g; leaching temperature is 70 °C; and hydrogen peroxide concentration is 3.0 %. More than 97 % Re was recovered under optimum leaching conditions of rhenium.

Keywords: Lead Dusts, Copper, Zinc, Rhenium, Leaching.

INTRODUCTION

Rhenium is an uncommon refractory metal. It has principal applications in industries due to its multiple valences and its ability to make super-hard alloys.¹,² The industrial demand for rhenium is drastically increasing due to its wide use in high-tech industry. In nature, rhenium does not have its minerals, so it occurs in the form of isomorphic inclusions in copper and molybdenum ores, and is also present in smaller quantities in uranium deposits.³-⁵ Therefore, it is very important to recover from various raw materials containing traces of rhenium. A large amount of dust-gas mixture is formed during the copper smelting process. This mixture is known to contain rhenium (Re₂O₇) as well as various gases (e.g. SO₂, SO₃).⁶,⁷ Hence, dusts of copper sulfide smelting process are considered a resource for rhenium recovery. Since rhenium is enriched in waste of mineral processing plants, copper production wastes, and slags, it is considered as an additional rhenium source.⁸,⁹ Depending on the content and form of rhenium in the raw material, various technological methods of its recovery are proposed.¹⁰-¹² Nowadays production of rhenium from lead dusts (LD) constantly improving. This interest is due to three facts 1) the dusts have a significant rhenium content, 2) dusts available for processing, and 3) the cost of raw materials is very low.

There are miscellaneous recycling methods of lead dusts including water leaching, acid leaching (atmospheric, autoclave, electrochemical) of raw materials in presence of various oxidants. The choice of leaching reagent depends on the chemical composition of the raw material. It can be solutions of sulfuric acid, hydrochloric acid, nitric acid, and sodium salts in presence of an oxidant.¹³,¹⁴ Oxidative roasting processes are also considered as perspective technologies of LD processing. The main goal of roasting processes is to convert the lowest rhenium valence compounds (ReO₃, ReS₂, etc.) to rhenium heptoxide (Re₂O₇) to produce rhenium-containing solutions.¹⁵
Compared to the pyrometallurgical processes hydrometallurgical processes are eco-friendlier because it emits nothing, is cost-effective, and saves energy. Therefore, in this study, rhenium containing dusts of copper production has been valorized applying two-stage leaching. The primary task of this study was to research the extraction of rhenium, zinc and copper from LD using sulphuric acid under atmospheric conditions to understand the effect of sulphuric acid concentration, leaching temperature, leaching time and liquid-to-solid ratio.

**EXPERIMENTAL**

**Material and Methods**

The LD sample was obtained from electric furnaces from Zhezkazgan copper melting factories in Kazakhstan. XRF analysis was used to determine the chemical composition of samples. The main components of lead dust are lead, copper and zinc (Table-1). The rhenium content is 0.0312 % or 312 g / t.

**General Procedure**

All leaching experiments were carried out in a temperature-controlled three-necked flat bottom glass flask (cap. 250 mL) on a hot-plate cum magnetic stirrer at fixed rpm (400) and a reflux condenser to avoid the...
loss due to evaporation. At the first stage of leaching, the applicability of water and sulfuric acid leaching was studied. The leaching time was recorded after successive addition of the LD and sulfuric acid solution to the reaction vessel, and then put this vessel in an oil bath maintained at a preset temperature (temperature range is 20-90 °C). The second leaching stage was performed by usage of 3-9 % hydrogen peroxide solution in water. After each leaching experiment, the residue was filtered, rinsed with distilled water and dried in an oven at 75 °C. The experiments were repeated three times to obtain reproducible results with an accuracy of 0.5 %.

Detection Method
The chemical composition of LD was analyzed using an iCAP 7200Duo inductively coupled plasma emission spectrometer. The phase composition of LD in terms of lead, copper, and zinc was determined by chemical phase analysis. The rhenium content in the processed products was determined using a spectrophotometric method based on the reaction of the rhenium complex of rhenium by a KFK-3-01-ZOMZ photocolorimeter. The chemical composition of the leach solutions was analyzed on an Agilent Technologies 200 GTA 120 Graphite Tube Atomiser 240Z AA atomic absorption spectrometer.

RESULTS AND DISCUSSION
Water leaching experiments were performed to clarify the influence of temperature and leaching time on the recovery of copper, zinc and rhenium into the solution (Figs.-2 and 3). The obtained results revealed that the copper and zinc almost completely dissolved at low leaching temperature so that sulfate compounds have high dissolution properties. However, maximum recovery degree of metals was observed only under these leaching conditions: t=60-80 °C; S: L=1:5 g/mL; time = 60 minutes. Under these conditions, recovery of metals was 72 % of Cu, 83 % of Zn, and 20.3 % of Re.

The volume of the pregnant leach liquor is 491 mL, metals content was determined as 5.03 g Cu/L, 20.8 g Zn/L, and 12.8 mg Re/L. As can be seen, the recovery degree of non-ferrous metals does not exceed 90 %, which indicates the solubility of only sulphate compounds. To obtain satisfactory results on the recovery of valuable components from LD, further studies on leaching were performed by usage of sulfuric acid at a concentration of 20-110 g/L (figure 4). The degree of zinc recovery in the solution increased by 10-11 % compared to water leaching and reached 92.5 %. on leaching of LD by sulfuric acid solutions with a concentration of 20-50 g/L and a temperature of 40 °C. Under these conditions, the degree of copper recovery reached 84 %. Increasing the concentration of sulfuric acid to 80-110 g/L caused 90.5 % leaching of copper. On the other hand, it was seen that the rhenium resolution decreased up to 15.3 %. Concentration values of copper, zinc, and rhenium were determined as 68.0 g/L, 23.6 g/L, and 9.6 mg/L, respectively, whereas the sulfuric acid concentration decreased from 80 g/L to 20 g/L. These findings showed that
although sulfuric acid was used more than stoichiometric amount, all of the metals could not be taken into solution. It was also understood that there are major acid-consuming compounds are target metals in the solid material.

During sulfuric acid leaching of LD, the dissolution behavior of other metals was also investigated. The chemical composition of the leaching solution at S: L=1:3 and leaching temperature of 60 °C is shown in table 3. It seems that the dissolution of other metals is quite low under these conditions.

The low degree of recovery of rhenium compared to non-ferrous metals is due to its forms of presence in LD in the form of lower oxide compounds. The results also showed that the rhenium in LD consists of different oxidation stages. To increase the degree of rhenium recovery, the presence of an oxidizer in leaching solutions is required. In previous research reported that hydrogen peroxide is proposed as an effective oxidizer, during the decomposition, not polluted solutions.\textsuperscript{16,17} It is shown that hydrogen peroxide is a temperamental aggravate, the disintegration of which can be catalyzed by certain variables, for example, the nearness of corrosive, base, mineral surface. Sulfuric acid leaching was performed in the presence of hydrogen peroxide. More than 90 % recovery of rhenium was achieved in the study conducted in presence of an oxidant. Due to the high content of copper and zinc in the solutions of sulfuric acid leaching and their negative impact on the extraction-stripping of rhenium (contamination of the commercial rhenium salts with impurities of copper and zinc, etc.), we decided to conduct two-stage leaching. The first stage is sulfuric acid leaching with the recovery of copper and zinc, and the second stage is oxidative leaching of rhenium. It was observed that the dissolution of metals increased in the two-step leaching method. The leach waste obtained from oxidative leaching in which 94.3 % of rhenium was recovered from first stage leaching residue was characterized. Chemical composition was found as 42.1 % Pb, 0.99 % Zn, 0.35 % Cu, 1.2 % As, 0.2 % Si, and 0.028 % Re. Based on semi-quantitative X-ray phase analysis of leaching waste, there are no peaks corresponding to zinc sulfate (Fig.-6).

The residue of first stage leaching was subjected to second stage leaching with 3-9 % solutions of hydrogen peroxide at 60 °C and S : L=1:3. By leaching the leach residue with a 6 % solution of hydrogen peroxide for 60 minutes, the maximum rhenium recovery is achieved as 96.1 %. A similar result (95.6 %) can be achieved by leaching with a 3 % solution of hydrogen peroxide for 90 minutes (Fig.-7). An application of H\textsubscript{2}O\textsubscript{2} distinctly improves rhenium leaching, but an increase in the concentration of hydrogen peroxide in
the leaching solution above 6 % does not lead to an increase in the extraction of rhenium into the solution. It is assumed that this limitation is due to an insufficient oxidizing strength of H$_2$O$_2$. Therefore, 3 % solution of hydrogen peroxide was selected as optimum concentration for rhenium extraction from first stage leaching residue. The studies of S : L ratio and leaching temperature showed that 97.3 % of rhenium was extracted under conditions of 70 °C and S:L=1:3. Also, a similar result was obtained at 60 °C and S : L=1:5 (Fig.-8).

Nevertheless, to obtain more rhenium-concentrated solutions, it is proposed to conduct a leaching process at 70 °C, S : L=1:3 with a 3 % solution of hydrogen peroxide. Chemical composition of the resulting solution, g / L: 0.092 Re, 0.011 Cu, 0.06 Zn, 0.8 Pb, 0.9 As. The resulting solutions are sent to the processes solvent extraction process. The developed flowsheet (technological scheme) of hydrometallurgical processing of LD is shown in Fig.-9.

**CONCLUSION**

As a result of studies of hydrometallurgical processing of lead dust of copper production, a method for 2-stage leaching of raw materials has been developed. At the first stage of sulfuric acid leaching, copper and zinc ions were converted to a solution with recovery rates of 90.3 % and 92.5 %, respectively. At the second stage of oxidative leaching, rhenium pregnant leach solutions with a recovery degree of 97.3 % were
obtained. Processing of rhenium-containing lead dusts by two-stage leaching allowed to obtain separate solutions of copper and zinc with their content of 10-11 g/L and 38-39 g/L, respectively, and solutions containing 90-92 mg/L of rhenium.
