#### Abstract

To analyze the geometrical and topological parameters of the3-MDPYP molecule, the quantum chemical calculations using Density Function Theory (DFT) is performed. This method along with the $6-311 \mathrm{G}^{* *}$ basis set, confirms the exact geometry of the selected molecule. The vital role of Piperidin-4-ones and its derivatives are found to have great potential in terms of becoming potent compounds in drug design. In this regard, characterizing such compounds to study theoretically and their structure becomes important and economical in performing the suitability test. This paper is a record of such research attempt on studying geometrical properties like the bond angle, bond lengths, torsion angles and bond topological properties of the 3-MDPYP molecule.

## INTRODUCTION

In today's drug discovery, it is a task challenging to understand the drug-receptor interaction ${ }^{1}$. Many methods have been proposed in the previous years to investigate the drug-receptor interactions ${ }^{2}$. However, in silico computer modeling techniques along with in vitro studies are playing an important role and helps confirm the drug-receptor mechanism. Always the drug and receptor molecules will have complementary charges, so that the drug molecule may be well inside the binding pocket of the receptor ${ }^{3,4}$. The drug-receptor plays an important role in three-dimensional structures and also in the atomic level interaction of the molecule ${ }^{5}$. It is based on the strength of electrostatic interaction and charge distribution of atoms in the binding of sites. Further, the same electrostatic interaction of molecule is used to verify the variable regions of the active drug molecule. This regard could be clarified through the accurate calculation of topological and electrostatic parameters determined from multipole analysis ${ }^{6}$ of charge density distribution of the molecule, which includes the effects of lone pair and p-electron density. So the understanding of charge density distribution is important to determine the molecular properties and to predict the intermolecular interactions ${ }^{7}$.
This work explains the theoretical analysis of charge density distribution and some topological parameters of the 3-MDPYP molecule through quantum chemical calculations. In today's scenario, Piperine-4-one compounds play a prime activity in all areas of drug discovery and form important drugs with an essential molecular structures ${ }^{8-13}$. These are reported to possess analgesic ${ }^{8}$, anti-inflammatory ${ }^{9}$, central nervous system $^{10}$, local analgesics ${ }^{11}$, anticancer ${ }^{12}$ and antibacterial activity ${ }^{13}$. To explore this kind of activity in 3MDPYP molecule, some theoretical operations with the help of DFT are performed. A clear idea of charge density distribution and topological properties of this molecule has allowed realizing the strength of intermolecular interactions and electrostatic interactions between the drug candidate and receptor which facilitate to examine the interactions of drug-receptor.

The current investigation which explains the charge density distribution of 3-MDPYP molecule from the high-level quantum chemical calculations combined with Bader's theory of Atoms in Molecules (AIM theory) ${ }^{14}$. The arrangement of the atoms in the selected molecule from AIM theory allows extracting the topology of electron density and electrostatic properties of the above molecule. The arrival of ultrashorter wavelength radiation ${ }^{15}$, synchrotron sources and area detectors are made to evaluate the molecular charge density distribution of small molecules to macromolecules ${ }^{16}$.
In recent year, charge density analysis becoming an important tool to interpret the molecular structures obtained from crystalline materials ${ }^{17}$. The information obtained from the topological analysis is significant and better than the molecules having classical atomic connectivity. Based on these values, it is confirmed that the 3-MDPYP molecule is apt for the effective candidate for drug-receptor activity.

## EXPERIMENTAL

## Computational Details

The 3-MDPYP molecule was obtained from laboratory source and the position of the atom in this molecule was confirmed by Density Functional methods ${ }^{18}$ using the Gaussian03 program ${ }^{19}$. A combination of Becke's three parameters exchange and Lee, Yang and Parr gradient-corrected correlation function (B3LYP) is applied for the whole DFT calculation along with $6-311 \mathrm{G}^{* *}$ basis set, which provided the effective core potential and the detailed description. The position of the atom in the regarding molecule was performed via Berny algorithm in redundant internal co-ordinates ${ }^{20}$.
The electron density $\rho_{\mathrm{bcp}}(\mathrm{r})$, Laplacian of electron density $\nabla^{2} \rho_{\mathrm{bcp}}(\mathrm{r})$, bond ellipticity $\varepsilon$ and the eigen values $\lambda_{i}$ were calculated using EXT94b routine incorporated to the AIMPAC software ${ }^{21}$. The Laplacian of charge density and the deformation density maps were plotted using DENPROP and wfn2plots program packages ${ }^{22}$.

## RESULTS AND DISCUSSION

## Structural Aspects

DFT is an effective method to evaluate the geometrical parameters such as bond lengths, bond angles and torsion angles using 6-311G类* basis set. The ball and stick model of energy minimized geometry of 3MDPYP molecule is shown inFig.-2. In-depth investigation of the geometrical parameters and the bond, distances are predicted using DFT method and are shown in this Table-1.
The calculated $\mathrm{C}-\mathrm{C}$ bond lengths in piperidine ring C1-C6 varied from $1.511 \AA$ to $1.568 \AA$ and similarly the C-C bonds in phenyl rings between $1.389 \AA$ to $1.403 \AA$. The distance of C5-C17 is $1.534 \AA$ which is similar to the reported structure ${ }^{23}$. Bond lengths of C2-N3 [1.466 A ] and N3-C4 [1.466 $\AA$ ] are moderately longer than $\mathrm{N} 8-\mathrm{C} 9$ [1.393 $\AA$ ] and $\mathrm{C}=\mathrm{N}$ bond distance is $1.185 \AA$. Nitrogen heteroatoms influence the bond length values of the molecule. Because of C6-N7 [1.393 $\AA$ ] and N7-N8 [1.348 $\AA$ ] bonds are comparatively lesser than other C-C bonds. The optimized structure of 3-MDPYP molecule is shown in the Fig. 2 and its atom-numbering scheme is indicated. The $\mathrm{C}-\mathrm{H}$ bond distances calculated from $1.081-$ $1.104 \AA$. The mean plane calculation of the ring system confirms that the molecule is a non-planar ${ }^{24}$.

## Charge Density Analysis

The deformation density map shows the arrangement of the electron density of atoms in 3-MDPYP molecule, which is used to visualize the areas of charge accumulation in the bonding regions and

## RASĀYAN J. Chem.

Vol. 11 | No. 1 |127-134 | January - March | 2018
positions of the heteroatoms. This map reveals that the 3-MDPYP having covalent nature of bonds from the continuous region of charge density distribution. A complete spectrum of charge density distribution obtained from the bond topological analysis of 3-MDPYP molecule is presented in the Table-2. Although the $\mathrm{N}-\mathrm{C}$ and $\mathrm{C}-\mathrm{C}$ bonds exhibit covalent interaction, its charge density distribution is not similar to the other bonding regions of the molecule; the map clearly differentiates the difference among the charge density distribution of various bonding regions of the molecule.

The charge accumulation of $\mathrm{C}_{\text {ar }}-\mathrm{C}_{\text {ar }}$ bond ranges from 1.536 to $2.094 \mathrm{e}^{\circ}{ }^{-3}$, which is slightly lower than N atoms attached to $\mathrm{C}-\mathrm{C}$ bond from 1.782 to $2.434 \mathrm{e}^{-3}$ of the 3 -MDPYP molecule. The low $\rho_{\mathrm{bcp}}(\mathrm{r})$ of $\mathrm{C}-\mathrm{C}$ bond is due to the effect of neighboring atoms in the molecule. $\mathrm{N}-\mathrm{N}$ bond density ranges around 2.447 $\mathrm{e} \AA^{-3}$ and $\mathrm{N}-\mathrm{H}$ bond $2.323 \mathrm{e}^{-3}$ which are comparatively higher than $\mathrm{C}-\mathrm{C}$ bonds and $\mathrm{C}-\mathrm{H}$ bonds respectively. Further, the $\mathrm{C}=\mathrm{N}$ bond density is $2.434 \mathrm{e}^{\circ} \AA^{-3}$, this implies that the strong bond observed in this molecule. The loan pair region of N -atoms is shown in the Fig.-3. The bond ellipticity, $\varepsilon=\left(\lambda_{1} / \lambda_{2}-1\right)$ is defined as the measure of anisotropy of electron distribution at BCP , where $\lambda_{1}$ and $\lambda_{1}$ are the negative eigenvalues of Hessian matrix ${ }^{25}$. The anisotropy of bond density $\rho_{\mathrm{bcp}}(\mathrm{r})$ is confirmed by the high ellipticity values. The ellipticity of $\mathrm{C}=\mathrm{N}$ bond is found to be higher and the value is $0.326 \AA$ The Laplacian of electron density, $\nabla^{2} \rho_{\mathrm{bcp}}(\mathrm{r})$, at the bond critical points of the molecule bears the chemical significance of the bond topological theory ${ }^{26}$.

Fig.-2: The optimized structure of 3-MDPYP molecule
The Laplacian of the electron density is negative for all bonds in the molecule and exhibits bond-critical points. As it is noticed in the previous section, the charge accumulation is not same as for all $\mathrm{C}-\mathrm{C}$ bonds of the aromatic ring. A similar trend can also be seen in the Laplacian of electron density distribution. The Laplacian values for $\mathrm{C}-\mathrm{C}$ bonds ranges from -11.3 to -20.8 e $\AA^{-5}$, of which the Laplacian values of N $\mathrm{N}, \mathrm{C}-\mathrm{N}, \mathrm{N}-\mathrm{H}, \mathrm{C}=\mathrm{N}$ bonds are -16.71 e $\AA^{-5},-16.322$ e $\AA^{-5},-39.724$ e $\AA^{-5}$ and -14.357 e $\AA^{-5}$ respectively.In Fig. -4 the contour map of Laplacian of electron density derived from the experiment, reveals that the C-C, $\mathrm{C}-\mathrm{N}, \mathrm{N}-\mathrm{H}$ and $\mathrm{C}-\mathrm{H}$ bonds of the 3-MDPYP molecule and confirms the covalent bond character.

Table-2: Bond topological properties of the3-MDPYP molecule at DFT/6-311G** level theory.

| Bonds | Rho(r) | D2r | $\lambda 1$ | $\lambda 2$ | $\lambda 3$ | $\varepsilon$ | V(r) | G(r) | H(r) | d1 | d2 | D | del_d\% |

Fig.-3: Deformation density maps of 3-MDPYP molecule drawn at (A) 2-Phenyl ring (B) 4-Ylidine Phenyl ring (C) 6-Phenyl ring and (D) Piperidine ring. Contours are drawn at 0.05 e $\AA^{-3}$ intervals. The solid lines (blue) are positive, dashed (red) are negative and dotted lines are zero contours. Contour intervals are drawn at $0.05 \mathrm{e}^{-3}$

Fig.-4: Laplacian of electron density maps of the 3-MDPYP molecule shown at (A) 2-Phenyl ring (B) 4-Ylidine Phenyl ring (C) 6-Phenyl ring and (D) Piperidine ring. Solid lines indicate positive contours, and dashed lines are negative contours $\mathrm{e}^{\AA-5}$.

## CONCLUSION

The bond topological and electrostatic properties of the energetic 3-MDPYP molecule are carefully evaluated by ab initio (DFT) calculation. The optimized geometric parameters obtained from the DFT/6$311 \mathrm{G}^{*}$ basis set is excellent in agreement with the similar type experimental data. For the calculation of $\mathrm{C}=\mathrm{N}$ and $\mathrm{N}-\mathrm{H}$ bonds have low charge accumulation at the bond critical point, which indicates the charge depletion of the molecule. This analysis gives effective results for the molecule by using AIM theory. From the bond topological properties and the energy density distribution, it confirms that C-N and N-H bonds are the weakest bonds in the molecule. In the case of aromatic $\mathrm{C}_{\mathrm{ar}}-\mathrm{C}_{\mathrm{ar}}$ bonds, reveals that these bonds are also considerably weak. Further, the $\mathrm{C}_{\mathrm{ar}}-\mathrm{C}_{\mathrm{ar}}$ and $\mathrm{C}-\mathrm{N}$ bonds are more sensitive than the other bonds in the molecule. Molecular docking study of this 3-MDPYP molecule and its results also found to be least when compared with the DHFR protein ${ }^{27}$. Two prominent hydrogen bonds are observed between the drug molecules and binding site residues such as Thr56, Ser59 with the bond distance of $2.10 \AA, 2.40$ $\AA$ A respectively and it is confirmed that these two bonds are the weakest bonds in the molecule. Thus, it can be concluded that the present study reveals the fine details of structural, charge density distribution and the electrostatic properties which are very convenient one for designing the new piperidone-based drugs for cancer therapeutics.
