#### Abstract

The polarographic determination of stability constants of metal complexes of $\operatorname{Pb}(I I)$ with Pyridine under varying temperatures at 303 K and 313 K in aqueous medium at 0.1 M KCL and at constant pH , have shown the formation of 1:1, 1:2, and 1:3 complexes. The values of stability constants of complexes have been calculated by Deford and Humes method and compared by values calculated by Mihailovs method (mathematical).The changes thermodynamic parameters $\Delta G, \Delta H$ and $\Delta S$ accompanying complexation have been also evaluated at $30^{\circ} \mathrm{C}$. The reduction process of $\mathrm{Pb}(\mathrm{II})$ in presence of Pyridine was found to be reversible and diffusion controlled involving two electron transfer. The formation constants, $\log \beta_{1}$ $\log \beta_{2}$ and $\log \beta_{3}$ of $\mathrm{Pb}(I I)$-Pyridine system at 303 K are $5.114,7.699$ and 7.699 and at 313 K are $5.068,7.623$ and 11.140 in aqueous medium. It was found that the stability constants of $\mathrm{Pb}(\mathrm{II})$ Pyridine system at 303 K is more than at the 313 K .

Keywords: Electrochemical Studies,Pyridine,Mihailov method.

## INTRODUCTION

From the survey of chemical literature ${ }^{1-10}$, it has been found that there are very few references in literature regarding polarographic studies of the complexation of Pb (II) with some amino acids at different temperatures. The polarographic behaviour of some of the amino acids viz Aspartic acid, Glutamic acid, etc., have already been studied by Saxena and Cowokers ${ }^{11}$. Number of electrochemical studies on the behaviour of amino acids and their complexes ${ }^{12}$ has been found useful applications in biochemistry and medicine ${ }^{13 .}$ Present study shows the complexation of $\mathrm{Pb}(\mathrm{II})$ with Pyridine an heterocyclic compound which have not been studied.

## EXPERMENTAL

Pyridine was supplied by B.D.H. Chemicals Ltd Poole England and all reagents were of Anal grade. Polarograms were recorded on a manual polarograph using a saturated calomel electrode as the reference electrode. The capillary had the following characteristics $\mathrm{m}=1.96 \mathrm{mg}, \mathrm{t}=4.10 \mathrm{sec}$ /drop and their stock solutions were prepared in conductivity water. Potassium chloride was used, as a supporting electrolyte to maintain the ionic strength at 1 M . The temperature was maintained constant at 303 K . A thermostat having an accuracy of $\pm 0.1^{\circ} \mathrm{C}$ was used to constant temperature of all solution $.0 .002 \%$ Tritron X-100 was used as a maximum suppressor and all polarograph were recorded in an inert atmosphere of Nitrogen at 303K and 313K. Experiments were performed with 0.5 mM of metal ion and Pyridine was used as complexing agent whose concentration was varied from 0.001 to 0.007 moles. The $\mathrm{E}_{1 / 2}$ of reduction of metal ligand complex showed a gradual cathodic shift with an increasing ligand concentration. The corresponding plot of $\mathrm{E}_{1 / 2}$ versus $-\log \mathrm{Cx}$ was smooth curve indicating successive complexation .

DeFord and Hume method hasbeen applied to determine the composition of metal ligand ratio and overall stability constants of metal complexes

## RESULTS AND DISCUSSION

The reduction of $\mathrm{Pb}(\mathrm{II})$ complexes with complex with ligand gives well defined wave at d.m.e. The plot of $\mathrm{I}_{\mathrm{d}} \mathrm{vs}_{\mathrm{e}_{\mathrm{eff}}}^{1 / 2}$ was found to be linear indicating the diffusion controlled nature of the electrode process. Conventional value of slope indicating the reversible nature of the electrode process involving two electron transfer process. Plots of $\mathrm{F}_{0}[\mathrm{X}], \mathrm{F}_{1}[\mathrm{X}], \mathrm{F}_{2}[\mathrm{X}]$, and $\mathrm{F}_{3}[\mathrm{X}]$ verses $[\mathrm{X}]$ when extrapolated to $[\mathrm{X}]=0$ gave the value of overall stability constant. The plot of $\mathrm{F}_{3}[\mathrm{X}]$ is horizontal to the $[\mathrm{X}]$ axis indicating the formation of three complexes with metal to ligand ratio of 1:1,1:2 and 1:3. Stability constants values are also calculated by Mihailov's method given in Table4 and are compared with the values of stability constants calculated by DeFord and Hume's method given below at both the temperatures 303 K and 313 K .

Calculations of Constants at $\mathbf{3 0 3 K}$

| Method | $\log \boldsymbol{\beta}_{\mathbf{1}}$ | $\boldsymbol{\operatorname { l o g }} \boldsymbol{\beta}_{\mathbf{2}}$ | $\boldsymbol{\operatorname { l o g }} \boldsymbol{\beta}_{\mathbf{3}}$ |
| :---: | :---: | :---: | :---: |
| DeFord and Hume | 5.114 | 7.699 | 11.238 |
| Mihailov | 4.761 | 8.075 | 11.213 |

Calculations of Constants at $\mathbf{3 1 3 K}$

| Method | $\log \boldsymbol{\beta}_{\mathbf{1}}$ | $\log \boldsymbol{\beta}_{\mathbf{2}}$ | $\log \boldsymbol{\beta}_{\mathbf{3}}$ |
| :---: | :---: | :---: | :---: |
| DeFord and Hume | 5.068 | 7.623 | 11.140 |
| Mihailov | 4.715 | 8.004 | 11.116 |

## Effect of Temperature:

It is seen from Table 1and Table 2 that stability constants gradually decreases with rise in temperature showing there by that lower temperature favours the formation of stable complexes . The reduction of $\mathrm{Pb}(\mathrm{II})$ ligand complex gives well defined cathodic wave (diffusion controlled) and reversible in each case . $\mathrm{E}_{1 / 2}$ versus $-\log \mathrm{Cx}$ was smooth curve indicating successive complexation. The $\log \beta$ values were determined at different temperature 303 K and 313 K which are summarized in Table 1 and Table 2, respectively.

## Thermodynamic Parameters:

Thermodynamic functions such as Free energy ( $\Delta \mathrm{G}$ ), Entropy $(\Delta \mathrm{S})$ and Enthalpy ( $\Delta \mathrm{H}$ ) accompanying complexation are determined at 303 K with the help of standard equation. The values of these thermodynamic functions are given in Table 3. The negative values of $(\Delta \mathrm{G})$ shows that the reaction tends to proceed spontaneously. The negative value of $(\Delta \mathrm{H})$ indicate the exothermic nature of reaction process in fair agreement with increasing stability suggesting
lower temperature favours the chelation process. The entropy values indicate that complexation is favoured by enthalpy and entropy factors.

## ACKNOWLEDGEMENT

One of the author (Ms Meena ) is thankful to Head, Department of Chemistry, University of Rajasthan, Jaipur for providing facilities to carry out this research.
