#### Abstract

The geometric parameters and theoretical vibrational frequencies of 3-Ethoxy-4-hydroxybenzaldehydeare calculated using HartreeFock (HF)method with $6-31 \mathrm{G}(\mathrm{d}, \mathrm{p}$ ) basis set and Density functional theory (B3LYP) methods with 6$31++\mathrm{G}(\mathrm{d}, \mathrm{p})$ and $6-311++\mathrm{G}(\mathrm{d}, \mathrm{p})$ basis sets. The detailed interpretation of the vibrational spectra has been carried out with the aid of normal coordinate analysis following the scaled quantum mechanical force field methodology (SQM). The UV absorption spectra of the title compound in the solvents, water and ethanol, are recorded in the range of $200-400 \mathrm{~nm}$. NBO analysis is also carried out to find out the intra-molecular electronic interactions and their stabilization energy. The highest occupied molecular orbital (HOMO) and lowest unoccupied molecular orbital (LUMO) energies are also found. Thermodynamic properties like entropy, heat capacity and zero point energy have been calculated for the title molecule. The Molecular Electrostatic Potential (MESP) analysis reveals the sites for electrophilic attack and nucleophilic reactions in the molecule.

## INTRODUCTION

3-Ethoxy-4-hydroxy benzaldehyde (EHB) is commonly known as ethyl vanillin, which is atrisubstituted benzene with - $\mathrm{CHO},-\mathrm{OCH}_{2} \mathrm{CH}_{3}$ and -OH groups substituted at $1,3,4$ positions of the ring. Ethyl vanillin is a chemically synthesized flavouring agent related to vanillin or artificial vanilla. Ethyl vanillin is widely used as a fragrance in cosmetics and as a flavour enhancer in food production (chocolate, candies, biscuits, instant noodles and bread), beverage and animal feed. It is also used in the electroplating industry, and as a brightener to whiten paper and fabric. Ethyl vanillin is used as an intermediate reagent in the synthesis of many drugs.
The vibrational spectra of the 3-methoxy-4-hydroxybenzaldehyde (vanillin) had already been interpreted by Gunasekaran and Ponnusamy ${ }^{1}$ on the basis of normal coordinate analysis. Several vibrational spectroscopic studies on mono-, di-, tri- substituted benzaldehydes have been reported ${ }^{2-7}$.The vibrational spectral data of isomeric benzaldehyde and dihydroxybenzaldehyde have been calculated based on normal coordinate analysis by Singh etal. ${ }^{8}$. Although much work has been done on substituted benzaldehydes, a comprehensive study of EHB on electronic structure along with the detailed potential energy distribution of normal modes of vibrations has not been reported so far. In the present study, the molecular structure, geometric parameters and vibrational frequencies of EHB are calculated using HF/6-31G (d, p), B3LYP/6-31++G (d, p) and B3LYP/6-311++G (d, p) basis sets and compared with the experimental data. The redistribution of electron density (ED) in various bonding, anti-bonding orbitals and $\mathrm{E}(2)$ energies have been calculated by Natural Bond Orbital (NBO) analysis to give clear evidence of
stabilization originating from the hyper conjugation of various intra-molecular interactions. HOMO-LUMO analysis has been used to elucidate information regarding charge transfer within the molecule. The Molecular Electrostatic Potential (MEP), thermodynamic properties and Mulliken charge analysis have also been studied. The UV-Vis spectrum of EHB is measured in ethanol and water solvents.

## EXPERIMENTAL

The 3-Ethoxy-4-hydroxy benzaldehyde compound was purchased from Sigma-Aldrich Company (USA) with a stated purity of $98 \%$ and it was used as such without further purification. The FT-IR spectrum of molecule was recorded in the region $4000-450 \mathrm{~cm}^{-1}$ using Perkin Elmer RXI spectrometer. FT-Raman spectra were recorded in the range of $4000-50 \mathrm{~cm}^{-1}$ using BRUKER, model RFS spectrophotometer. The UV absorption spectra were recorded in ethanol and water solvents in the region 200-400 nm using Perkin Elmer LAMDA UV-Vis NIR spectrometer.

## Computational Details

The DFT computation of EHB had been performed using Gaussian 03 program package ${ }^{9}$ at HF method with $6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ and DFT (B3LYP) method with $6-31++\mathrm{G}(\mathrm{d}, \mathrm{p})$ and $6-311++\mathrm{G}(\mathrm{d}, \mathrm{p})$ basis sets. The optimized structural parameters were evaluated for the calculations of vibrational frequencies at different methods. The harmonic vibrational frequencies had been analytically calculated by taking the second order derivative of energy using the same level of theory. Normal co-ordinate analysis had been performed in order to obtain the detailed interpretation of the fundamental modes using the MOLVIB program version 7.0 written by Sundius ${ }^{10,11}$. The scaling of the force field was performed according to the scaled quantum mechanical procedure $(\mathrm{SQM})^{12,13}$ using selective scaling in the natural internal coordinate representation ${ }^{14,15}$ to obtain a better agreement between the theory and the experiment. The Raman activities $\left(\mathrm{S}_{\mathrm{i}}\right)$ calculated by the Gaussian 03W program and converted into relative Raman intensities ( $\mathrm{I}_{\mathrm{i}}$ ) during the scaling program with MOLVIB using the following relationship was derived from the basic theory of Raman scattering ${ }^{16,17}$.

$$
\begin{equation*}
\mathrm{I}_{\mathrm{i}}=\frac{\mathrm{f}\left(v_{\mathrm{o}}-v_{\mathrm{i}}\right)^{4} \mathrm{~S}_{\mathrm{i}}}{v_{\mathrm{i}}\left[1-\exp \left(\frac{-\mathrm{hc} v_{\mathrm{i}}}{\mathrm{kT}}\right)\right]} \tag{1}
\end{equation*}
$$

Where $v_{0}$ is the exciting wave number $\left(\mathrm{cm}^{-1}\right)$ of laser light source used while recording Raman spectra, $v_{i}$ is the vibrational wave number of the $\mathrm{i}^{\text {th }}$ normal mode; $\mathrm{h}, \mathrm{k}, \mathrm{c}$ and T are Planck and Boltzmann constants, speed of light and temperature in Kelvin respectively. F is the suitably chosen common normalization factor for all the peak intensities.
The NBO calculations ${ }^{18}$ were performed using NBO 3.1 program as carried out in the Gaussian 03 W package at the DFT/B3LYP level in order to understand the various second order interactions between the filled orbitals and vacant orbitals.The electronic absorption spectra for optimized molecule were calculated with the time dependent density functional theory (TD-DFT) at B3LYP/6-311++G (d, p) level.

## RESULTS AND DISCUSSION

## Molecular geometry

The optimized geometry structure of the title compound is shown in Fig 1. The optimized bond lengths, bond angles and dihedral angles calculated by HF/6-31G(d,p) and DFT-B3LYP level with $6-31++\mathrm{G}(\mathrm{d}, \mathrm{p})$, $6-311++G(d, p)$ basis sets are compared with the experimental data and are presented in Table 1.In the substitution of the aldehyde and hydroxyl groups, the bond lengths C1-O8(1.213 $\AA$ ) and $\mathrm{C} 5-\mathrm{O} 9(1.362 \AA)$ calculated by B3LYP/6-311++G(d,p) are in good agreement with the experimental values for the title
molecule and are close to the literature value ${ }^{19} 1.208 \AA / 1.359 \AA$. The bond angle C2-C3-C4(121.41 $)$ is larger than C3-C4-C5(118.694 $)$ due to the substitution of ethoxy group.

Table-1: Experimental (XRD) and optimized geometrical parameters of EHB computed at HF/6-31G (d, p), B3LYP/6-31++G (d, p) and B3LYP/6-311++G (d, p) basis sets.

## Vibrational analysis

A detailed vibrational description has been carried out with the help of normal coordinate analysis. Internal coordinates have been described according to Pulay's recommendations. A non-redundant set of local symmetry coordinates constructed by suitable linear combinations of internal coordinates suggested by Rahut and Pulayand are presented in Table2. Vibrational frequencies have been calculated using HF/6-

31G (d, p), B3LYP/6-31++G (d, p) and B3LYP/6-311++G (d, p) basis sets. The calculated FT-IR and Raman vibrational wave numbers and assignments of EHB are given in Table 3, along with the experimental values. The experimental and theoretical FT-IR and FT-Raman spectra of the title compound are shown in Figs 2 and 3.

Table-2: Definition of local symmetry coordinates for EHB

${ }^{\mathrm{a}}$ Atom numbering as in Fig.-1.
${ }^{b}$ Definitions are made in terms of the standard valence coordinates: $r_{i j}$ is the bond length between atoms $i$ and $j$ : $\beta_{\mathrm{ijk}}$ is the valence angle between $\mathrm{i}, \mathrm{j}, \mathrm{k}$ where j is the central atom: $\gamma_{\mathrm{ijk} 1}$ is the out-of-plane angle between the $\mathrm{i}-\mathrm{j}$ bond and the plane defined by the j.k.l atoms: $\tau_{\mathrm{ijk} k}$ is the torsion (dihedral)angle between the plane defined by $\mathrm{i}, \mathrm{j}, \mathrm{k}$ and $\mathrm{j}, \mathrm{k}, 1$ atoms: $\mathrm{a}=\cos 144^{\circ}$ and $\mathrm{b}=\cos 72^{\circ}$ (v)stretching:( $\beta$ )in-plane-bending:( $\gamma$ )out-of-plane-bending:( $\tau$ )torsion.

## C - H vibrations

In substituted benzene rings, the C-H stretching vibrations ${ }^{20}$ give rise to bands at $3120-3000 \mathrm{~cm}^{-1}$. The C-H vibrations of the title compound are observed at 3089,3065 and $3024 \mathrm{~cm}^{-1}$ in the FT-IR spectrum and at 3088,3068 and $3028 \mathrm{~cm}^{-1}$ in the FT-Raman spectrum. The corresponding calculated wave numbers at $3074,3043,3023 \mathrm{~cm}^{-1}$ and at $3085,3061,3036 \mathrm{~cm}^{-1}$ and at $3087,3063,3039 \mathrm{~cm}^{-1}$ by $\mathrm{HF} / 6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$, B3LYP/6-31++G(d,p) and B3LYP/6-311++G(d,p) levels respectively, show good agreement with observed bands of EHB. The in- plane aromatic C-H deformation vibrations ${ }^{21}$ occur in the region 1300$1000 \mathrm{~cm}^{-1}$. The bands are sharp but are of weak to medium intensity. The medium and strong intensity bands at 1197 and $1041 \mathrm{~cm}^{-1}$ in the FT-IR spectrum and at $1198 \mathrm{~cm}^{-1}$ in the FT-Raman spectrum are due to in-plane deformations. The C-H in-plane bending vibrations are calculated at $1209,1083,1046 \mathrm{~cm}^{-1}$ by

HF/6-31G (d,p) and at $1196,1074,1040 \mathrm{~cm}^{-1}$ and at $1209,1071,1051 \mathrm{~cm}^{-1}$ by B3LYP/31++G(d,p) and B3LYP/311++G(d,p) levels respectively. Bands involving the out-of-plane hydrogen bending vibrations ${ }^{22}$ absorb in the range $1000 \mathrm{~cm}^{-1}$ to $675 \mathrm{~cm}^{-1}$. The C-H out-of-plane bending vibrations are calculated at 915 , $862,830 \mathrm{~cm}^{-1}$ by HF/6-31G (d, p) and at $913,872,833 \mathrm{~cm}^{-1}$ and $904,847,818 \mathrm{~cm}^{-1}$ by B3LYP/6-31++G (d, p), B3LYP/6-311++G (d, p) basis sets respectively. The observed peaks at 903,852 and $839 \mathrm{~cm}^{-1}$ in the FT-IR spectrum due to C-H out-of-plane bending vibrations are in good agreement with the calculated values by HF/6-31G(d,p), B3LYP/6-31++G(d,p) and B3LYP/6-311++G(d,p) basis sets.

## C - C vibrations

The ring carbon - carbon stretching vibrations occur in the region $1625-1430 \mathrm{~cm}^{-1}$. In general, the bands are of variable intensity and are observed at $1625-1590 \mathrm{~cm}^{-1}, 1590-1575 \mathrm{~cm}^{-1}, 1540-1470 \mathrm{~cm}^{-1}, 1465-$ $1430 \mathrm{~cm}^{-1}$ and $1380-1280 \mathrm{~cm}^{-1}$ from the frequency ranges given by Varsanyi ${ }^{23}$, for the five bands in the region. In the present work, the frequencies observed in the FT-IR spectrum at 1603, 1578, 1515 and $1398 \mathrm{~cm}^{-1}$ and at 1602,1577 and $1517 \mathrm{~cm}^{-1}$ in the Raman spectrum have been assigned to $\mathrm{C}-\mathrm{C}$ stretching vibrations. The theoretically computed values at $1615,1592,1502,1415,1356,1320 \mathrm{~cm}^{-1}$ by HF/6$31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ and at $1599,1586,1497,1411,1346,1305 \mathrm{~cm}^{-1}$ by B3LYP/6-31++G(d,p) and at 1589,1574 , $1502,1411,1333,1309 \mathrm{~cm}^{-1}$ by B3LYP/6-311++G(d,p) method for C-C vibrational modes give good agreement with the experimental data. The weak bands observed at 737 and $634 \mathrm{~cm}^{-1}$ in the FT-IR and at 735,635 and $461 \mathrm{~cm}^{-1}$ in the FT-Raman are assigned to CCC deformations of phenyl ring. The calculated values are at $747,642,456 \mathrm{~cm}^{-1}$ by HF/6-31G ( $\mathrm{d}, \mathrm{p}$ ) and at $740,635,455 \mathrm{~cm}^{-1}$ by B3LYP/6-31++G ( $\mathrm{d}, \mathrm{p}$ ) method.

Fig.-2: Experimental (A), Simulated (B),(C) and (D) Infrared spectra of EHB at HF/6-31G(d,p),B3LYP/6$31++G(d, p)$ and B3LYP/6-311++G(d,p) levels.

## Aldehyde group vibrations

The C-H stretching vibrations of aldehyde group ${ }^{24}$ usually appear in the region $2806-2871 \mathrm{~cm}^{-1}$. In the present work, the weak band observed in the FT-IR spectrum at $2796 \mathrm{~cm}^{-1}$ is due to the C-H stretching vibration of the aldehyde group. The C-H stretching vibration computed at $2817 \mathrm{~cm}^{-1}$ by $\mathrm{HF} / 6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ and at $2792 \mathrm{~cm}^{-1}$ by B3LYP/6-31++G(d,p) method and at $2785 \mathrm{~cm}^{-1}$ by B3LYP/6-311++G(d,p) for EHB shows good agreement with the recorded value. The in-plane CH deformation mode of aldehyde group occurs at $1300 \mathrm{~cm}^{-1}$. In EHB, the in-plane CH deformation mode of aldehyde group is observed at
$1043 \mathrm{~cm}^{-1}$ with weak intensity in the FT-Raman spectrum. The calculated wave number at $1056 \mathrm{~cm}^{-1}$ by $\mathrm{HF} / 6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ and at $1044 \mathrm{~cm}^{-1}$ by B3LYP/6-31++G( $\left.\mathrm{d}, \mathrm{p}\right)$ and at $1059 \mathrm{~cm}^{-1}$ by B3LYP/6-311++G(d,p) method is attributed to CH in-plane deformation mode. The carbonyl( $\mathrm{C}=\mathrm{O}$ ) stretching vibrations ${ }^{25}$ in the substituted benzaldehydes are reported near $1700 \mathrm{~cm}^{-1}$. The strong band centred at $1686 \mathrm{~cm}^{-1}$ in the FT-IR and at $1684 \mathrm{~cm}^{-1}$ in the FT-Raman are attributed to the $\mathrm{C}=\mathrm{O}$ stretching vibrations of the aldehyde group of EHB. The theoretically calculated value is at $1678 \mathrm{~cm}^{-1}$ by HF/6-31G (d, p) and at $1686 \mathrm{~cm}^{-1}$ by B3LYP/6$31++G(d, p)$ and at $1687 \mathrm{~cm}^{-1}$ by B3LYP/6-311++G (d, p) method. Singh et al. ${ }^{9}$ have assigned the C=O in-plane bending vibrations for methoxybenzaldehydes in the region $585-620 \mathrm{~cm}^{-1}$. Hence the weak band observed at $585 \mathrm{~cm}^{-1}$ in the FT-IR and at $587 \mathrm{~cm}^{-1}$ in the FT-Raman spectrum could be assigned to $\mathrm{C}=\mathrm{O}$ in plane bending vibration. The calculated value is at $588 \mathrm{~cm}^{-1}$ by HF/6-31G ( $\mathrm{d}, \mathrm{p}$ ) and B3LYP/6-31++G ( d , p) methods and at $593 \mathrm{~cm}^{-1}$ by B3LYP/6-311++G (d, p) method. Gunasekaran et al. ${ }^{26}$ have assigned the band at $188 \mathrm{~cm}^{-1}$ in the Raman spectrum of 3-methoxy-4-hydroxybenzaldehyde as aldehyde out-of-plane wag. In EHB, the weak band centred at $183 \mathrm{~cm}^{-1}$ in the Raman spectrum could be due to aldehyde out-ofplane wagging vibration. The theoretically computed value is at $197 \mathrm{~cm}^{-1}$ by HF/6-31G ( $\mathrm{d}, \mathrm{p}$ ) method and at $185 \mathrm{~cm}^{-1}$ by both B3LYP/6-31++G (d, p), 6-311++G (d, p) basis sets. A weak to medium intensity band due to aldehyde group CHO deformation vibration ${ }^{27}$ is found in the region $975-780 \mathrm{~cm}^{-1}$. The out of plane C-H deformation mode of aldehyde group is observed at $970 \mathrm{~cm}^{-1}$ with medium intensity in the FT-IR spectrum and at $975 \mathrm{~cm}^{-1}$ in the FT-Raman spectrum for EHB. The calculated value at $971 \mathrm{~cm}^{-1}$ by $\mathrm{HF} / 6-$ $31 \mathrm{G}(\mathrm{d}, \mathrm{p})$, B3LYP/6-31++G (d, p) methods and at $972 \mathrm{~cm}^{-1}$ by B3LYP/6-311++G (d, p) method agree well with the experimental values.

Fig.-3: Experimental (A), simulated (B), (C) and (D) Raman Spectra of EHB at HF/6-31G (d,p), B3LYP/6$31++G(d, p)$ and B3LYP/6-311++G(d,p) levels.

## $\mathbf{O}$ - $\mathbf{H}$ vibrations

The OH group gives rise to three vibrations, namely, stretching, in-plane bending and out-of-plane bending. The precise position of $\mathrm{O}-\mathrm{H}$ band depends on the strength of hydrogen bond. The O-H stretching ${ }^{28}$ appears at $3500-3300 \mathrm{~cm}^{-1}$ in the intra-molecular hydrogen bonded systems. In the present work, the O-H stretching is found at $3363 \mathrm{~cm}^{-1}$ in the FT-IR spectrum and calculated at $3386 \mathrm{~cm}^{-1}$ by HF/6$31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ and at $3363,3365 \mathrm{~cm}^{-1}$ by B3LYP/6-31++G(d,p), $6-311++\mathrm{G}(\mathrm{d}, \mathrm{p})$ methods respectively. The inplane bending vibration ${ }^{29,30}$ of OH occurs in the region $1400-1200 \mathrm{~cm}^{-1}$. The strong absorption at $1104 \mathrm{~cm}^{-1}$ in FT-IR spectrum agrees well with the calculated wave number at $1107 \mathrm{~cm}^{-1}$ by $\mathrm{HF} / 6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$
and at $1101 \mathrm{~cm}^{-1}$ by both B3LYP/6-31++G(d,p) and B3LYP/6-311++G(d,p) methods. The out-of-plane bending mode of OH is assigned to a medium band at $524 \mathrm{~cm}^{-1}$ in both FT-IR and FT-Raman spectra. The calculated wave number is at $528 \mathrm{~cm}^{-1}$ by HF/6-31G $(\mathrm{d}, \mathrm{p})$ and at $514 \mathrm{~cm}^{-1}$ by B3LYP/6-31++G $(\mathrm{d}, \mathrm{p})$ and at $507 \mathrm{~cm}^{-1}$ by B3LYP/6-311++G(d,p) method.

Table-3: Comparison of the experimental (FT-IR and FT-Raman) wave numbers $\left(\mathrm{cm}^{-1}\right)$ and theoretical wave numbers ( $\mathrm{cm}-1$ ) of EHB calculated by HF/6-31G (d. p), B3LYP/6-31++G (d, p) and B3LYP/6-311++G (d, p) basis sets.

## Ethoxy vibrations

The five ethyl C-H stretching vibrations absorb between 2995 and $2855 \mathrm{~cm}^{-1}$ with a moderate to strong intensity. The normal vibrations are usually arranged in order of descending wave number $v_{\mathrm{a}} \mathrm{Me} \geq$ $v_{\mathrm{a}}{ }^{*} \mathrm{Me} \geq v_{\mathrm{a}} \mathrm{CH}_{2} \geq v_{\mathrm{s}} \mathrm{Me} \geq v_{\mathrm{s}} \mathrm{CH}_{2}$. The $\mathrm{CH}_{3}$ asymmetric stretching vibrations occur at $2975-2950 \mathrm{~cm}^{-1}$ and may easily be distinguished from the nearby $\mathrm{CH}_{2}$ absorption at about $2930 \mathrm{~cm}^{-1}$. The symmetric $\mathrm{CH}_{3}$ stretching absorption band ${ }^{31}$ occurs at $2885-2865 \mathrm{~cm}^{-1}$ and that of the methylene group at $2870-2840 \mathrm{~cm}^{-1}$. In EHB, both the asymmetric and symmetric stretching vibrations of $\mathrm{CH}_{3}$ group have been calculated at 2979, 2957 and $2886 \mathrm{~cm}^{-1}$ by HF/6-31G ( $\mathrm{d}, \mathrm{p}$ ) and B3LYP/6-31++G ( $\mathrm{d}, \mathrm{p}$ ), 6-311++G (d, p) methods. The C-H asymmetric stretching vibrations of a $\mathrm{CH}_{3}$ group are observed at 2979 and $2957 \mathrm{~cm}^{-1}$ in the FT-IR and 2981 and $2959 \mathrm{~cm}^{-1}$ in the FT-Raman spectra respectively while symmetric stretching vibration of $\mathrm{CH}_{3}$ is assigned at $2886 \mathrm{~cm}^{-1}$ in FT-IR and at $2888 \mathrm{~cm}^{-1}$ in the FT-Raman spectrum of EHB. The presence of adjacent electronegative atoms or groups can alter the position of the methyl symmetric band significantly, its range being $1470-1260 \mathrm{~cm}^{-1}$ whereas the asymmetric band is far less sensitive its range being $1485-1400 \mathrm{~cm}^{-1}$. The asymmetrical methyl deformation modes are obtained at $1439 \mathrm{~cm}^{-1}$ in the FTIR and at 1460 and $1441 \mathrm{~cm}^{-1}$ in the FT-Raman spectrum of EHB. The asymmetrical methyl deformation modes calculated at $1467,1453 \mathrm{~cm}^{-1}$ by the HF/6-31G ( $\mathrm{d}, \mathrm{p}$ ), $1460,1439 \mathrm{~cm}^{-1}$ by the B3LYP/6-31++G ( d , p) and $1463,1432 \mathrm{~cm}^{-1}$ by the B3LYP/6-311++G (d, p) methods, which show good agreement with the experimental values. The symmetrical methyl deformational mode of EHB assigned both in FT-IR and FT-Raman spectra at $1380 \mathrm{~cm}^{-1}$,agrees well with the calculated values at 1385,1380 and $1376 \mathrm{~cm}^{-1}$ by HF/6-31G(d,p), B3LYP/6-31++G(d,p) and B3LYP/6-311++G(d,p) methods respectively. The $\mathrm{CH}_{3}$ rocking vibration in ethoxy derivatives has been assigned to the region $1190-1108 \mathrm{~cm}^{-1}$. The rocking vibration of the $\mathrm{CH}_{3}$ group has been calculated at $1123 \mathrm{~cm}^{-1}$ by $\mathrm{HF} / 6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ and at $1117 \mathrm{~cm}^{-1}$ by B3LYP/6-31++G(d,p) and at $1131 \mathrm{~cm}^{-1}$ by B3LYP/6-311++G(d,p) method. This vibration shows good agreement with FT-IR and FT-Raman recorded values at $1115 \mathrm{~cm}^{-1}$ and $1117 \mathrm{~cm}^{-1}$. The $\mathrm{CH}_{3}$ torsional mode ${ }^{32}$ is expected in the region $235 \pm 25 \mathrm{~cm}^{-1}$. The observed wave number in FT-Raman at $220 \mathrm{~cm}^{-1}$ assigned to the $\mathrm{CH}_{3}$ torsional mode of EHB , shows good agreement with the computed wave number at $221 \mathrm{~cm}^{-1}$ by HF/6-31G(d, p) and at $220 \mathrm{~cm}^{-1}$ by both B3LYP/6-31++G(d,p), B3LYP/6-311++G(d,p) methods.
The $\mathrm{CH}_{2}$ anti-symmetric stretching vibration is generally observed in the region $3000-2900 \mathrm{~cm}^{-1}$, while the $\mathrm{CH}_{2}$ symmetric stretch ${ }^{33,34}$ will appear between 2900 and $2800 \mathrm{~cm}^{-1}$. The band at $2934 \mathrm{~cm}^{-1}$ is assigned to $\mathrm{CH}_{2}$ asymmetric stretching in both FT-IR and FT-Raman spectra which shows good agreement with the calculated value $2934 \mathrm{~cm}^{-1}$ by $\mathrm{HF} / 6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$, B3LYP/6-31++G(d,p) and B3LYP/6-311++G(d,p) methods. The theoretically predicted value at $2865 \mathrm{~cm}^{-1}$ by HF/6-31G (d, p), B3LYP/6-31++G (d, p) and B3LYP/6-311++G ( $\mathrm{d}, \mathrm{p}$ ) methods is attributed to $\mathrm{CH}_{2}$ symmetric stretching, which agrees well with the experimental value at $2865 \mathrm{~cm}^{-1}$ in the FT-IR spectrum. The fundamental $\mathrm{CH}_{2}$ vibrations such as scissoring, wagging, twisting and rocking ${ }^{35}$ appear in the frequency region $1500-800 \mathrm{~cm}^{-1}$. The scissoring mode of $\mathrm{CH}_{2}$ group gives rise to a characteristic band at $1477 \mathrm{~cm}^{-1}$ in the FT-IR and at $1478 \mathrm{~cm}^{-1}$ in the FTRaman spectrum of EHB, which agrees well with the calculated value at $1485 \mathrm{~cm}^{-1}$ by $H F / 6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ and
at $1476,1477 \mathrm{~cm}^{-1}$ by B3LYP/6-31++G(d,p), $6-311++G(\mathrm{~d}, \mathrm{p})$ basis sets respectively. The methylene wagging mode in ethoxy compounds expected in the region $1350 \pm 40 \mathrm{~cm}^{-1}$ is with moderate to strong intensity. In EHB, the wagging vibrational band of $\mathrm{CH}_{2}$ mode is recorded at 1279 and $1281 \mathrm{~cm}^{-1}$ as a strong and medium band in FT-IR and FT-Raman spectrum respectively and its corresponding calculated value is $1299 \mathrm{~cm}^{-1}$ by $\mathrm{HF} / 6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ and at $1289 \mathrm{~cm}^{-1}$ by B3LYP/6-31++G $(\mathrm{d}, \mathrm{p})$ and at $1270 \mathrm{~cm}^{-1}$ by B3LYP/6-311++G(d,p). The methylene twist is located in the region $1285 \pm 45 \mathrm{~cm}^{-1}$ with a weak to moderate intensity. The $\mathrm{CH}_{2}$ twisting mode in the FT-IR is observed at $1168 \mathrm{~cm}^{-1}$ and at $1163 \mathrm{~cm}^{-1}$ in the FT-Raman spectrum of EHB. The theoretically computed $\mathrm{CH}_{2}$ twisting mode is at $1180 \mathrm{~cm}^{-1}$ by $\mathrm{HF} / 6-31 \mathrm{G}$ $(\mathrm{d}, \mathrm{p})$ and at $1168 \mathrm{~cm}^{-1}$ by B3LYP/6-31++G(d,p) and at $1176 \mathrm{~cm}^{-1}$ by B3LYP/6-311++G(d,p) method. The medium peak at $786 \mathrm{~cm}^{-1}$ both in FT-IR and FT-Raman is assigned to the $\mathrm{CH}_{2}$ rocking mode of EHB. The $\mathrm{CH}_{2}$ rocking mode predicted at $782 \mathrm{~cm}^{-1}$ by HF/6-31G(d,p) and at $786 \mathrm{~cm}^{-1}$ by B3LYP/6-31++G(d,p) and at $789 \mathrm{~cm}^{-1}$ by B3LYP/6-311++G(d,p) method show excellent agreement with the experimental data.

## Natural bond orbital (NBO) analysis

The NBO analysis is carried out by considering all possible interactions between filled donor and empty acceptor NBOs, and estimating their energetic importance by second-order perturbation theory. NBO analysis has been performed on the title molecule at the DFT/B3LYP/6-311++G (d, p) level in order to elucidate the intra-molecular and delocalization of electron density within the molecule. The hyperconjugative interaction energy can be deduced from the second order perturbation approach.
$\mathrm{E}^{(2)}=\Delta \mathrm{E}_{\mathrm{ij}}=\mathrm{q}_{\mathrm{i}} \mathrm{F}(\mathrm{i}, \mathrm{j})^{2} / \varepsilon_{\mathrm{j}}-\varepsilon_{\mathrm{i}}$
Where $\mathrm{q}_{\mathrm{i}}$ is the $\mathrm{i}^{\text {th }}$ donor orbital occupancy, $\varepsilon_{i}, \varepsilon_{\mathrm{j}}$ are diagonal elements (orbital energies) and $\mathrm{F}(\mathrm{i}, \mathrm{j})$ is the off-diagonal NBO Fock-matrix element. The larger the $\mathrm{E}^{(2)}$ value the more intensive is the interaction between electron donors and electron acceptors, i.e., more donating tendency from electron donors to electron acceptors and greater the extent of conjugation of the whole system .

Table-4: Second order perturbation theory analysis of fock matrix in NBO basis for EHB.

| Donor(i) | ED(i)(e) | Acceptor (j) | ED (j) (e) | $\begin{aligned} & \hline \mathrm{E}(2)^{\mathrm{a}} \\ & (\mathrm{kcal} / \mathrm{mol}) \end{aligned}$ | $\mathrm{E}(\mathrm{j})-\mathrm{E}(\mathrm{i})^{\text {b }}$ (a.u) | $\mathrm{F}(\mathrm{i}, \mathrm{j})^{\mathrm{c}}$ (a.u) |

The most important interaction in this molecule is electron donating from O9LP (2) to the anti-bonding $\pi^{*}$ (C5-C6) resulting in a stabilization of $28.09 \mathrm{kcalmol}^{-1}$. All lone pair-bond pair interactions and bond pair-bond pair interactions with stabilization energy above $3 \mathrm{kcalmol}^{-1}$ are listed in Table 4. In EHB molecule, the bond pair donor orbital $\pi_{\mathrm{CC}} \rightarrow \pi^{*}{ }_{\mathrm{CC}}$ interaction between the $\mathrm{C} 5-\mathrm{C} 6$ bond pair and $\mathrm{C} 2-\mathrm{C} 7$ anti-bonding orbital gives the strongest stabilization of $23.42 \mathrm{kcalmol}^{-1}$. Likewise, $\pi(\mathrm{C} 2-\mathrm{C} 7) \rightarrow \pi^{*}(\mathrm{C} 3-\mathrm{C} 4)$ and $\pi(\mathrm{C} 3-\mathrm{C} 4) \rightarrow \pi^{*}(\mathrm{C} 5-\mathrm{C} 6)$ interactions give strong stabilization energies 22.81 and $22.37 \mathrm{kcalmol}^{-1}$ respectively. $\mathrm{O} 8 \mathrm{LP}(2)$ transfers the stabilization energy to $\sigma^{*}(\mathrm{C} 1-\mathrm{C} 2), \sigma^{*}(\mathrm{C} 1-\mathrm{H} 13)$ with $\mathrm{E}^{(2)}$ energy of about 17.46 and $23.11 \mathrm{kcalmol}^{-1}$ respectively as shown in Table 4.

## Frontier molecular orbital analysis

The frontier molecular orbitals play an important role in the electric and optical properties. The highest occupied molecular orbitals (HOMOs) and the lowest-lying unoccupied molecular orbitals (LUMOs) are named as frontier molecular orbitals. The energy gap between HOMO and LUMO is very important in determining the chemical activity of the molecule. A small HOMO-LUMO energy gap implies low kinetic stability, because it is energetically favourable to add electrons to a low-lying LUMO and to receive electrons from a high-lying HOMO ${ }^{36-38}$. The energies of HOMO and LUMO and their orbital energy gaps are calculated using B3LYP/6-311++G(d,p) method and the pictorial illustration of the frontier molecular orbitals and their respective positive and negative regions are shown in the Fig 4for EHB. According to Fig.4, HOMO is mainly localized over the entire molecule except for methyl group. However, LUMO is characterized by a charge distribution on hydroxyl benzaldehyde except for ethoxy group. The HOMO $\rightarrow$ LUMO transition implies an electron density transfer from O atom. The HOMO and LUMO energies are - 0.24613 a.u. and - 0.07030a.u.in gas phase. The energy difference between the HOMO and LUMO is obtained as $0.17583 \mathrm{a} . \mathrm{u}$, which indicates the high stability of the molecule.

Fig.-4: HOMO and LUMO plot of EHB

## Molecular electrostatic potential

The MESP is a plot of electrostatic potential mapped onto the constant electron density surface and it simultaneously displays the molecular size, shape and electrostatic potential value in terms of colour coding. The total electron density mapped with the electrostatic potential surface of EHB constructed by the B3LYP/6-311++G(d,p) method is shown in Fig. 5. The MESP may be employed to distinguish regions on the surface which are electron poor (electrophilic attack) from those which are electron rich (nucleophilic attack). The different values of the electrostatic potential at the surface are represented by different colours; red represents the region of the most electronegative electrostatic potential, blue represents the region of the most positive electrostatic potential, green represents the region of zero potential and yellow represents slightly electron rich region. It is obvious from Fig. 5,that the region around the oxygen atom in the aldehyde group represents the negative potential region. The hydrogen atom attached in the hydroxyl group possesses positive charge. The predominance of green region in the ring surfaces and methyl group corresponds to a potential halfway between the two extremes red and blue colour. Hence the total electron density surface mapped with electrostatic potential reveals the presence of negative charge on the aldehyde oxygen while positive charge is present around the hydroxyl region.

Fig.-5: Molecular electrostatic potential map of EHB calculated at B3LYP/6-311++G (d, p) level.

## Thermodynamic properties

Theoretical geometrical parameters represent a good approximation and they are the basis for calculating vibrational frequencies and thermodynamic parameters. The frequency calculations compute the zero point energies, thermal correction to internal energy and entropy as well as the heat capacity for a molecular system. These functions describe the thermodynamic stability of the system at the given conditions of pressure and temperature. In order to clarify the relations among the energetic and structural reactivity of the title molecule, some calculated thermodynamic parameters (such as zero point vibrational energy, specific heat capacity, entropy, thermal energy, rotational constants and dipole moment) of EHB by DFT/B3LYP method at 298.15 K and 1.00atmpressure are listed in Table5. On the basis of vibrational analysis and statistical thermodynamics, the standard thermodynamic functions heat capacity $\left(\mathrm{C}_{\mathrm{p}}\right)$, entropy $(\mathrm{S})$ and enthalpy $\left(\Delta \mathrm{H}_{\mathrm{m}}\right)$ are obtained and listed in Table6. As observed from the Table, the values of heat capacity, entropy and enthalpy increase with the increase of temperature from 100 to 1000 K , which is attributed to the enhancement of molecular vibrations when the temperature increases.
According to the data in Table5 for the title compound, the correlations between the thermodynamic properties $\mathrm{C}_{\mathrm{p}}, \mathrm{S}$ and $\Delta \mathrm{H}_{\mathrm{m}}$ and temperatures T are described and shown in Fig 6. The correlation equations of the title compound are as follows:
$\mathrm{C}_{\mathrm{p}}=5.2969+0.15334 \mathrm{~T}-6.20388 \times 10^{-5} \mathrm{~T}^{2} . \quad\left(\mathrm{R}^{2}=0.99972\right)$
$\mathrm{S}=56.61203+0.18138 \mathrm{~T}-4.56742 \times 10^{-5} \mathrm{~T}^{2}$.
( $\mathrm{R}^{2}=0.99986$ )
$\Delta H_{m}=-3.26441+0.03036 \mathrm{~T}-3.19509 \times 10^{-5} \mathrm{~T}^{2}$.
( $\mathrm{R}^{2}=0.99585$ )

## Mulliken Atomic Charges

Mulliken population analysis is mostly used for the calculation of the charge distribution in a molecule ${ }^{39}$. Mulliken charges are calculated by determining the electron population of each atom as defined by the
basis set. The calculated mulliken charge values of EHB using the B3LYP/6-311++G (d,p) method are listed in Table.7. From Table 7, it is obvious that all the
hydrogen atoms have a net positive charge. The charge distribution of the title compound shows that the carbon atoms C3, C6 and C7 attached with hydrogen atoms are negative, whereas the remaining carbon atoms C2 and C5 are positively charged due to the substitution
of hydroxyl and aldehyde group. From the result, it is clear that the substitution of aromatic ring leads to a redistribution of electron density. The charge distribution on the molecule has an important influence on the vibrational spectra. ${ }^{40}$

Table-7: Mulliken Atomic Charges for EHB

| Atoms | Charges |
| :---: | :---: |
| C1 | -0.115 |
| C2 | 0.928 |
| C3 | -0.497 |
| C4 | -0.608 |
| C5 | 0.250 |
| C6 | -0.126 |
| C7 | -0.236 |
| O8 | -0.252 |
| O9 | -0.235 |

## UV-Vis analysis

The ultraviolet spectra analyses of EHB have been investigated in water and ethanol solvents by theoretical calculation. On the basis of fully optimized ground state structure, TD-DFT/B3LYP/6-311++G ( $\mathrm{d}, \mathrm{p}$ ) calculations have been used to determine the low-lying excited states of EHB. The theoretical electronic excitation energies, oscillator strengths and absorption wavelengths are listed in Table 8. Calculations of the molecular orbital geometry show that the absorption maxima of this molecule correspond to the electron transition between frontier orbitals such as transition from HOMO to LUMO. From Table.8, the calculated absorption maxima values have been found to be 228.51 nm and 271.5 nm for water solvent, 228.67 nm and 271.26 nm for ethanol solvent by B3LYP/6-311++G(d,p) method. The experimental results are observed at $233.6,266.4 \mathrm{~nm}$ and $233.4,266.6 \mathrm{~nm}$ for water and ethanol solvents respectively. These absorption maxima values are in good agreement with the theoretical values. The UVVis spectra of EHB were recorded in water and ethanol solvents as shown in Fig.-7.

Fig.-7: Experimental UV-vis spectra of EHB in ethanol and water solvents.
Table-8: Theoretical electronic absorption spectra of EHB (absorption wavelength $\lambda$ (nm), excitation energies E (ev) and oscillator strengths (f ) using TD - B3LYP/6-311++G(d,p) method in water and ethanol solvents.

| Experimental | Theoretical wavelength |  |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :---: | :--- | :--- | :---: |
|  | Water |  |  | Ethanol |  |  |  |
| Water | Ethanol | $\lambda(\mathrm{nm})$ | $\mathrm{E}(\mathrm{ev})$ | f | $\lambda(\mathrm{nm})$ | $\mathrm{E}(\mathrm{ev})$ | f |
| 266.4 | 266.6 | 271.50 | 4.5667 | 0.1851 | 271.26 | 4.5707 | 0.1841 |
| 233.6 | 233.4 | 228.51 | 5.4258 | 0.3230 | 228.67 | 5.422 | 0.3308 |

## CONCLUSIONS

Theoretical calculations have been carried out on $3-$ Ethoxy -4 - hydroxyl benzaldehyde(EHB) using HF/6-31G(d,p) and B3LYP/6-31++G(d,p), B3LYP/6-311++G(d,p) methods to explain the FT-IR and FTRaman spectra and structural properties. The vibrational frequency analysis by the B3LYP/6$311++G(d, p)$ method agrees satisfactorily with the experimental results. The NBO result reflects the charge transfer within the molecule. Also the HOMO and LUMO energies of EHB in the ground state have been calculated by using the density functional theory. The large HOMO-LUMO energy gap indicates the high chemical stability of the molecule. The MESP map shows that the negative potential sites are on oxygen atoms in the methoxy group and the aldehyde group as well as the positive potential site is on the hydrogen atom in the hydroxyl group. The UV-vis spectrum of EHB was measured in ethanol and water solvents. The TD-DFT calculations show a good agreement with the observed values. The thermodynamic functions in the range from 100 K to 1000 K are obtained. The gradient of heat capacity, entropy and enthalpy increases with the increase of temperature.
